Slides `SLIDES.md`

The complete framework end to end, exactly as the prospectus promises it: asset selection, buying zones, prudent borrowing mechanics, and the risk rules that protect you. This is the level where a person stops being interested and starts being able to compute.

This level must stand on its own. Someone who takes Level 1 and never buys anything else has to leave with something whole. Nothing is withheld to make the next level necessary — see `../_shared/ascension.md`.

`{{VARIABLE}}` comes from the cohort file. **[LIVE]** means read it off the platform in the room, never off the slide. **[LAYER A]** / **[LAYER B]** mark what transfers to future programmes — see `../_shared/layer-model.md`.

The 240-minute plan

Block	Minutes	Running
A · Open, house rules, disclosure	12	0:12
B · Frame the four modules	5	0:17
Module 1 · Buy Borrow Die	65	1:22
Break	10	1:32
Module 2 · Yen Carry Trade	40	2:12
Module 3 · Entry Levels	40	2:52
Break	10	3:02
Module 4 · Capital Preservation	40	3:42
E · Close and Q&A	18	4:00

Beat timings inside each module are the **floor**. Where a module has slack in the four-hour format, spend it on: the calculator moments in Module 1 (let every person finish), a second worked drill in Module 1, the unwind story in Module 2, and a second scenario in Module 3. Never spend it on the close.

BLOCK A · OPEN — 12 min

A1 · Welcome — 2 min · slide 1

Good evening everyone. Thank you for being here. We know you could be somewhere else tonight, and you chose to spend this time with us. On behalf of me, {{coaches}}, we appreciate it. Because you gave us your time, we'll give you our very best and make it worth it.

Is that okay with you? Type **Yes** in the chatbox.

Wait. Acknowledge what comes in. "Thank you, I see the Yes coming in."

A2 · House rules — 4 min · slide 2

Before we start — the house rules.

One, keep your questions until the end of each module. Two, mic off, camera on, so we can see your beautiful faces. Three, pressing question — chatbox. We answer after each module. Four, 100% participation. Learning needs positive energy. Five, prepare your calculators. And say this with me: **we love Math because we make Money.**

Everyone good with the house rules? Type **ready**.

Wait for the responses. "Here we go."

A3 · The standing disclosure — 5 min · slide 3

Read `_shared/risk-disclosure.md` §1 verbatim. Do not paraphrase, do not soften, do not add a joke at the end.

That's the last time tonight I'll be heavy. But it's the reason you can trust everything that comes after it.

BLOCK B · FRAME — 5 min · slide 4

Tonight, four modules.

One — **Buy, Borrow, Die**. Two — the **Yen Carry Trade**. Three — **Entry Levels**. Four — **Capital Preservation**, which is the one that keeps you in the game long enough for the first three to matter.

We'll discuss the principles first, and relate them to the Binance interface as we go. Because just like in Cashflow — you have to know the fundamentals, the gameplay, and how you move around the board before you play well.

Sound good? Type **Ok**.

Wait. "Let's go."

MODULE 1 · BUY BORROW DIE — 65 min

B1 · The land — 3 min · slides 5-6

Year 2021. You have **1 million pesos**. Someone offers you one hectare in BGC at 30% below market value. Would you buy it?

Type **Yes**.

Wait. "You just bought one hectare of land. Congratulations!"

Fast forward five years. That land is now worth **2 million pesos**.

Let them celebrate. Do not rush this.

B2 · The filter — 4 min · slide 7

Now. What are your options to make money out of this land? Raise your hand.

Take two or three real answers. Thank each one. If nobody says "borrow against it", filter:

All good answers. Here's the one we're after — you can **borrow** against it.

Who here is familiar with the word "refinancing"? With using land as "collateral"?

Thank you.

So how do you turn a 2-million-peso hectare into cash without selling it?

B3 · The bank walk — 12 min · slides 8-14 (single beat, seven build slides)

Walk the build one letter at a time. Let each step land before advancing.

A. You go to the bank. **B.** You fill up forms for a loan against your property. This is an **asset-backed loan** — a loan against something you own that has value. **C.** The bank assesses whether it's really worth 2 million. You pay an appraisal fee. **D.** Then due diligence. Is the title actually yours? Are your real estate taxes up to date? Your other government payments? **E.** Then you have to get **approved**. And even approved, banks only lend up to **80% loan-to-value**. Why do you think they cap it at 80%?

Take answers. Thank them. Reinforce:

Right — the bank makes sure it always comes out ahead. That's why only 80%.

F. Calculators out. What's 80% of 2 million?

Wait for the chat. "1.6 million. Correct."

G. Now you pay monthly amortisation on what you borrowed. **H.** And here's the question. Do you actually receive the full 1.6 million?

Take answers.

Correct — **may mga bawas pa yan**. Fees. Insurance. Credit loan protection.

Do you feel the hassle? The forms, the back and forth, making sure everything is in order? And after all that — you can still be denied. And if approved, you're on the hook for a monthly payment.

Type **hassle** in the chatbox.

Wait. "Thank you."

B4 · Foreclosure — 4 min · slide 15

What happens if one day you can't make the monthly amortisation?

The bank issues you this word. **Foreclosed.**

What happens to your property? Type it in the chat.

Take answers. "Thank you, thank you."

They take the asset, and they sell it. Note the timeline though — this takes **months**. You miss payments, you get notices, you get letters, you get chances. Hold that thought, because it's going to matter in about ten minutes.

B5 · The same shape, digitally — 5 min · slides 16-17

Now — how do we do this with cryptocurrency?

Physical real estate is land. **Digital real estate is Bitcoin.** Like land, you can own a fraction of it. Like land, you can borrow against it.

But with digital real estate you don't fill out forms. You don't travel to a bank. You don't wait on government agencies. You can't be rejected. And you don't pay appraisal fees or insurance — so you receive the whole amount you borrow.

Same platform to buy it, same platform to borrow against it.

Corrections C1, C2, C3 — say this, it replaces the old comparison slide:

Now let me be straight with you about the trade-off, because the honest version is more useful than the sales version.

Ticket size — land needs millions. This needs about `{{min_capital_php}}` pesos. Smaller money at stake.

Risk — and here I'm going to disagree with how this is usually sold. Less money exposed does **not** mean less risk. Bitcoin swings far harder than BGC land, and remember the foreclosure timeline? Months of notices? On this platform there are no notices and no months. If the price hits a number, the platform sells your Bitcoin.

Minutes, not months. Smaller ticket, faster and deeper downside.

Interest — [LIVE] read `{{usdt_borrow_apr}}` off the platform. That is not "very low". It's roughly what a Philippine bank charges on a secured loan — without the consumer protections.

"You never have to sell" — you are choosing not to sell *today*. The loan is still owed. You repay it from income, or you repay it from a later borrow, or eventually the platform sells for you. This strategy buys you **timing**. It does not buy you escape.

B6 · The numbers — 4 min · slide 18

Say you have **\$100**. Bitcoin is at **\$100,000** — I'm using a round number so the math is clean; [LIVE] today it's actually `{{btc_price_usd}}`.

\$100 buys you 0.001 BTC. And the platform will let you borrow up to **78%** of that instantly. [LIVE] verify `{{max_initial_ltv}}`.

Now — should you?

B7 · Why 78% ends you — 5 min · slides 19-21

Let's find out. You borrow at 78% LTV. Bitcoin drops 10% — from \$100,000 to \$90,000. Where's your LTV now?

Two ways to get there. The quick field check: add the drop to your LTV. 78 plus 10 is 88%. **The platform's actual math** divides instead: 78 divided by 0.90 is **86.7%**.

Write both down, and know the difference. The quick version always reads a little higher, so it errs on the safe side — but the app will show you the lower number and I don't want you thinking the app is lying to you.

Either way, you've crossed **85%**. That's a **margin call**. The platform tells you: repay, or add collateral.

Keep falling. At **91% LTV**, the platform stops asking. It **liquidates** — sells your Bitcoin to cover the loan. That's foreclosure, except it takes seconds and nobody sends you a letter.

A 10% Bitcoin drop is a Tuesday. That's what 78% LTV buys you.

B8 · The drills — 6 min · slides 22-25

Run both. Do not skip the losing one.

Drill one. You bought at **\$90,000**. You borrowed to **60% LTV**. Bitcoin drops to **\$50,000**. Liquidated or not? Calculators.

Step one, the drop: 90,000 minus 50,000 is 40,000. Step two, the percentage: 40,000 over 90,000, times 100 — **44%**. Step three, the new LTV: 60 divided by 0.556 — **108%**.

108 is well past 91. **Liquidated**. Your Bitcoin is gone.

Does a 44% drop happen in Bitcoin? **Yes**. It has happened in 2018, in 2021, in 2022. Not a black swan. A cycle.

Drill two. Same entry, \$90,000. This time you borrowed to **50%**. Bitcoin drops to **\$60,000**.

The drop: 30,000 over 90,000 — **33.3%**. New LTV: 50 divided by 0.667 — **75%**. 75 is under 91. **Not liquidated**. Give yourselves a hand.

B9 · The rule the old version got wrong — 4 min · slide 26

This is the most important beat in Module 1. Do not compress it.

Now here's where I'm going to correct something you may have heard elsewhere — including from us, in earlier cohorts.

The usual rule is "keep your LTV at or below 50% and you're fine." You just survived drill two at 50%, so it sounds right.

Run the arithmetic properly. At 50% LTV, you get liquidated at a **45% drawdown**.

Bitcoin's drawdowns: 2018, about **84%**. 2021, about **53%**. 2022, about **77%**.

50% LTV does not survive **any** of those. It survives a correction. It does not survive a bear market — and a bear market is exactly when your job, your business and your other money are also under pressure.

So the BBT rule is not 50%. It's this:

Position LTV — 30% or less. That survives a 67% drawdown. **Programme LTV — 20% or less.** Loan divided by your capital *plus your reserve*. **The reserve — for every 100 dollars you deploy, you hold 100 dollars back.**

Two different numbers, and you need to be able to say both of yours. Write them down now.

B10 · Break — 10 min · slides 27-28

Questions before the break? I'll take three.

Bound it. Take three. Then: "Ten-minute break. Music on. Be back."

MODULE 2 · YEN CARRY TRADE — 40 min

C1 · Re-entry — 2 min · slide 29

Still awake? Type **ready**. Thank you.

C2 · Japan, 1990 — 4 min · slide 30

1990s Japan. Economy is stagnant. They want investment into the country.

So the Bank of Japan makes a policy — a **zero interest rate policy**. Foreign investors can borrow yen at nearly zero percent, in exchange for putting money into Japan.

Countries borrowed. Institutions borrowed. Big investors borrowed. They saw the opportunity.

C3 · The trade — 6 min · slides 31-33

Here's what they did. Borrow in yen at 0%. Convert to US dollars. Buy US Treasury bills yielding 4%.

Calculators. Borrow **1 billion yen** at 0%. Rate is **159 yen to the dollar**. How many dollars?

About **6,289,000**. Put that in a 4% yield — what does it earn?

\$251,572. And what interest do you owe Japan? **Zero**.

The difference between what you earn and what you pay — 4% minus 0% — that gap is the **carry**. That's the trade.

C4 · The half nobody teaches — 6 min · slide 34

Correction C5. This beat did not exist in the old deck. It is the point of the module.

Now. I've just taught you the version that sells. Let me teach you the version that's true, because it's the version that keeps your money.

You borrowed **one billion yen**. What do you have to pay back?

Not dollars. **Yen**. One billion of them.

So what happens if the yen gets *stronger* while you're holding dollars? Your dollars now buy fewer yen. You need more of them to repay the same loan. Your 4% is gone — and past a point, your capital goes with it.

This isn't theory. In **August 2024**, the Bank of Japan raised rates. The yen surged. Everyone holding this trade had to unwind at once — sell the dollar assets, buy back the yen — all of them, on the same day. Japanese equities fell double digits. Global

markets fell. **Crypto fell.** Positions that had earned the carry for years gave it all back inside a week.

The trade the textbooks call clever is the same trade that blew up.

Now hold that, because here's the part that matters to you. When you run this strategy, you borrow a stablecoin **against your Bitcoin.** So your version of "the yen surges" is —

Wait for the room. Let someone say it.

Bitcoin falls. Same shape. Same failure mode. Same fix: keep the borrow small enough that the unwind can't reach you.

That's the 30%. That's the reserve. That's the whole reason we're strict about a number that looks boring.

C5 · Stablecoins — 4 min · slides 35-37

To play this, you need one thing first.

Sino dito naglaro na sa **Timezone**? If you walk in with 1,000 pesos, can you play immediately?

No — you convert it to **credits** first. Then you play.

Same here. **USDT** and **USDC** are the tokenised form of the US dollar. One dollar equals one USDT equals one USDC. Same value — different companies issue them. That's the difference.

C6 · The spread, honestly — 3 min · slide 38

Correction C4.

[LIVE] Here are today's rates. Borrow USDT at `{{usdt_borrow_apr}}`. Earn USDC at `{{usdc_earn_apr_headline}}`.

So you borrow the cheaper one and hold the one that earns more. Same idea the institutions ran with the yen.

Three things before you get excited.

One — that headline earn rate is **tiered**. It applies to the first tranche only, up to `{{usdc_earn_apr_tier_cap}}`. Above that you drop to a much lower rate. On your actual balance the blended rate is `{{usdc_earn_apr_blended}}`.

Two — both rates float, independently. The gap narrows. Some months it **inverts** and you pay more than you earn. In Level 4 you'll check this monthly and know what to do when it flips.

Three — the money earning that rate is sitting on a platform. That's its own risk and no strategy here protects you from it.

Today's real spread: `{{carry_spread}}`. That's the number. Not the headline.

C7 · The flow — 2 min · slides 39-40

Buy. Borrow. Convert. Earn. One step at a time, and we minimise risk at every step.

And you end up holding two things: your Bitcoin, *and* capital you didn't have before. That's the opportunity — which brings us to Module 3.

MODULE 3 • ENTRY LEVELS — 40 min

D1 • Recall — 3 min • slides 41-42

Two to three questions before Module 3.

Take them, bounded.

Who remembers the buying zones from **The Confident Investor's Blueprint**?

The Fibonacci buying zones. **0.618. 0.50. 0.382.** First level, second level, third level.

D2 • Why levels matter here — 4 min • slide 43

In TCIB these were about *entering well*. Here they do a second job.

Our purpose is to **accumulate** more digital real estate. So instead of selling at the next level up — you **borrow** against it.

D3 • The pattern — 5 min • slide 44

Look at the shape. You bought at 0.50. Price runs up to 0.618.

Price goes up. What do you do? Type it.

Wait for "borrow".

Borrow. Not sell. Then if price drops back into your levels, you use that borrowed capital to **buy more**.

Buy. Borrow. Buy. Borrow.

D4 • Scenario one, bought and it fell — 4 min • slide 45

\$100. You buy Bitcoin at **\$100,000** — round numbers. That's 0.001 BTC. You borrow **30%**. You now hold \$30 in USDT.

Bitcoin drops to **\$85,000**. What do you do? Type it.

Wait for "buy".

You buy. \$30 at \$85,000 is 0.00035 BTC.

Total holdings: 0.00135 BTC. You own **35% more Bitcoin** than you started with, and you never added new money.

D5 • Scenario two, bought and it rose — 4 min • slide 46

Same \$100 at \$100,000. This time price runs to **\$115,000**. Your position is worth \$115. You're up.

Instead of selling — what do we do? **Borrow.** 30% of \$115 is \$34.50.

Bitcoin comes back to \$85,000. You buy. \$34.50 buys 0.00041 BTC.

Total: 0.00141 BTC. More Bitcoin than scenario one — and you still hold the original position.

D6 • The catch, and the reserve — 4 min • slide 47

Correction C7. This was a speaker note in the old deck. It is now a slide.

Here's the catch, and it's the one that actually matters.

What if the price goes below your levels? Below 0.382? Below where your plan said it would stop?

That's when the reserve comes in. For every \$100 of capital you deploy, you hold **\$100 back**. Untouched. Not in the position. Not in Earn where you'd be tempted.

So with \$100 deployed and \$30 borrowed and \$100 in reserve — you're carrying \$130 of dry powder against a \$100 position. That is what lets you buy a 60% drawdown instead of being liquidated by it.

And one warning, because people get this backwards: if you're in a **margin call**, the top-up has to come from the **reserve**. Not from borrowing more. Buying more Bitcoin with borrowed money raises your loan and your collateral together — it does not rescue the position.

Level 2/3 is where we drill this until it's automatic.

D7 • No signal — 2 min • slides 48-50

What if there was no buying signal and you bought anyway?

Then **your buying price becomes your 0.618**. Plot your Fibonacci as normal, then move it so 0.618 sits on your entry.

But understand what you just did — this is **not encouraged**. Walang basehan yung Fibonacci mo if you just moved it to wherever you happened to buy. This only shows you your next levels *given* you already bought. It doesn't make a bad entry good.

SECOND BREAK — 10 min • slide 51

MODULE 4 • CAPITAL PRESERVATION — 40 min • [LAYER A]

New module, and the reason the other three are worth anything. Everything here is drawn from `../_shared/capital-preservation.md` — read it before you teach it, and verify the figures.

F1 • The sentence — 4 min • slide 52

Module 1 ended on a word: **foreclosed**. Let me give you the general version.

A drop is not a loss until you are forced to sell.

Say it back to me. Type it in the chat.

Everything in the next forty minutes is one question: how do we remove the force?

F2 • Where your alarms sit on the price — 10 min • slide 53

You already know 91% is liquidation. Let's turn that into prices you can actually watch.

Open at **30% LTV**. Calculators. What price fall takes you to 40% LTV?

30 divided by 0.75 is 40. So a **25% fall**. That's your first alarm.

Now 50% LTV — 30 over 0.6, so a **40% fall**. Now 60% — 30 over 0.5, a **50% fall**. And liquidation at 91% — a **67% fall**.

Price falls	LTV	What you do
–25%	40%	Log it. Nothing else.
–40%	50%	Calculate the top-up. Don't execute.
–50%	60%	ACT. Top up from reserve, or close the loan.
–67%	91%	Liquidation — <i>you never arrive here</i>

Look at the gap between the third row and the fourth. **Seventeen percentage points**, and a written instruction sitting inside it.

That gap is what you're actually buying with the discipline.

F3 · Seven years of weather — 8 min · slide 54

Walk the drawdown record. Verify the figures before the session.

2019, about –54%. 2020 COVID, about –63%. 2021, about –54%. 2022 — **–77%**. 2024, about –33%.

Roughly once a year, every year, for seven years.

Now match those to the table. Four of those five hit **Alarm 3**. Which tells you something you need to hear now rather than at 3am:

Alarm 3 is not an emergency. It is a normal event. It happens about once a year. Someone who thinks it's a catastrophe will panic. Someone who expects it will act.

F4 · The worst entry in seven years — 12 min · slide 55

The most important beat in Level 1. Do not compress it.

Let's try to break the rule. Worst possible entry — you bought at the **2021 peak, around \$69,000**. The exact top. And you followed our ceiling, 30% LTV.

Calculators. Your liquidation price: 69,000 times 0.30 divided by 0.91.

\$22,747.

Now — the 2022 low was about **\$15,500**.

Let the room do the comparison. Wait for it.

Yes. **You would have been liquidated.**

So let me say the thing plainly: **30% by itself does not save you**. Anyone who tells you "just keep LTV at 30" is telling you the same half-truth as "just keep it at 50", one rung up. I'm not going to be that person.

Now run it again with the whole rule set.

Price	Event	What you do
\$69,000	Open at 30%, reserve funded 1:1	—
\$51,750	–25% · Alarm 1	Log it
\$41,400	–40% · Alarm 2	Calculate the top-up
\$34,500	–50% · Alarm 3	Close the loan from reserve. Keep every satoshi.
\$22,747	<i>would have been liquidation</i>	Loan already closed. Nothing to sell.
\$15,500	The 2022 bottom	Still holding 100% of it

Your loan was 30% of what you deployed. Your reserve was 100% of it. Closing that loan cost you **less than a third of your reserve** — and it ended the risk completely. So what saved you? Not the number. **The instruction to act at minus fifty, written down while nothing was wrong.**

F5 · The honest half — 6 min · slide 56

Never skip. This is the credibility of the programme.

Now the part I'd rather you hear from me than find out yourself.

You still took the drawdown. At the bottom of 2022 that Bitcoin was worth about 23 cents on the peso. Our rules didn't stop that. Nothing stops that.

What they did was make sure **you still owned all of it**. So when it turned, it turned in your hands.

We preserve the asset. That's what lets you choose your own timing.

If you came here hoping we'd show you how to avoid red on a screen — we can't, nobody can, and anyone who says otherwise is selling you something. What we teach is how to still be holding when it comes back.

BLOCK E · CLOSE AND Q&A — 18 min

E1 · Where the two competing uses land — 3 min · slide 57

Correction C8. Without this the room leaves with a contradiction.

One thing to close cleanly. I showed you two different jobs for the same borrowed peso.

Module 2 said: borrow, convert, park it in Earn, collect the spread. Module 3 said: borrow, hold it, buy the dip.

You cannot do both with the same money. Splitting it properly needs a written allocation and pre-committed levels, and that's Level 2/3 work.

Until then: run the carry only. You're learning the mechanism, not chasing a return.

E2 · Q&A — 6 min

Questions. I'll take as many as we can fit in six minutes, and anything I don't reach, {{ops_lead}} will answer after.

Answer straight. Model answers for the hard ones are in `../_shared/facilitator-standard.md` §4. If anyone asks how much they'll make: no number, no range, no "historically".

E3 · The close — 9 min · slides 58-62

The five beats from `../_shared/ascension.md`.

Beat 1 · What you can now do — slide 58

Four hours ago most of you couldn't have told me what LTV stood for. Tonight you computed a liquidation price from a peak you didn't choose, and you found the one instruction that saved a position through a 77% drawdown.

That's not a small thing. Most people who own Bitcoin cannot do what you just did.

Beat 2 · The gap — slide 59

Here's what you still can't do.

Everything tonight was **on paper**. You have never funded a wallet, moved money between two platforms, posted collateral, or watched an LTV slider move with your own money behind it.

And there's a specific night coming. Bitcoin is down 40%, your phone is going off, it's 3am, and you have to act **in order**, correctly, tired. Tonight you learned that night exists. You haven't rehearsed it.

Reading the fire exit is not the same as walking it in the dark.

Beat 3 · The next level — slide 60

That's **Level 2/3 — the Deep Dive and the Immersion**. One curriculum, two ways to take it.

Online, three days, ₱15,000 — chart structure and levels, the platform, your first live position, LTV discipline, and the drill. You leave with a position at 30% LTV, four alarms set on your phone, and your liquidation price written in your own hand.

Face to face, three to four days, ₱75,000 — everything above, in a room, small class, plus your complete personal playbook built beside the faculty: your accumulation system, your three buckets, your operating plan.

Same principle either way. The room buys you the playbook and the attention.

Beat 4 · Who shouldn't take it — slide 61

Mandatory. Deliver it slowly.

Now — who should **not** book Level 2 or 3.

If you're not going to fund the reserve, don't come. You saw tonight what did the saving. It wasn't the ceiling, it was having money behind the position. Half the rule

set is worse than none, because it feels like protection and isn't. Come back when you can fund both sides.

If you're planning to use money you'll need inside five years, don't come.

Nothing we teach makes short money safe.

And if tonight made you excited rather than careful — sit with it a week.

Excitement is what puts people at 78% LTV. I'd rather you came to the next cohort calm than this one eager.

Those aren't disclaimers. If you're in that list I'd genuinely rather have your respect than your ₱15,000.

Beat 5 · One step — slide 62

Registration is in the chat. Next Deep Dive {{level_2_date}}, next Immersion {{level_3_date}}. Seats are capped at {{seat_cap}} because pods run one coach to eight and we don't stretch that.

If you're unsure which — or unsure at all — message {{ops_lead}} and say so. You'll get a real answer, including "not yet" if that's the real answer.

Thank you for four hours. Whatever you decide, take this home: **a drop is not a loss until you're forced to sell.**
